

Growing technological opacity and the social brain

François Osiurak

University of Lyon, Lyon, France

Institut Universitaire de France, Paris, France

Opacity

Opacity can be defined as the degree to which information is ***not accessible*** for cognitive processing.

Mechanically transparent

Mechanically opaque

Subjective

It depends on individual characteristics or experience

Opacity

....can take several forms

How was this object made?

*What knowledge do others
have of it?*

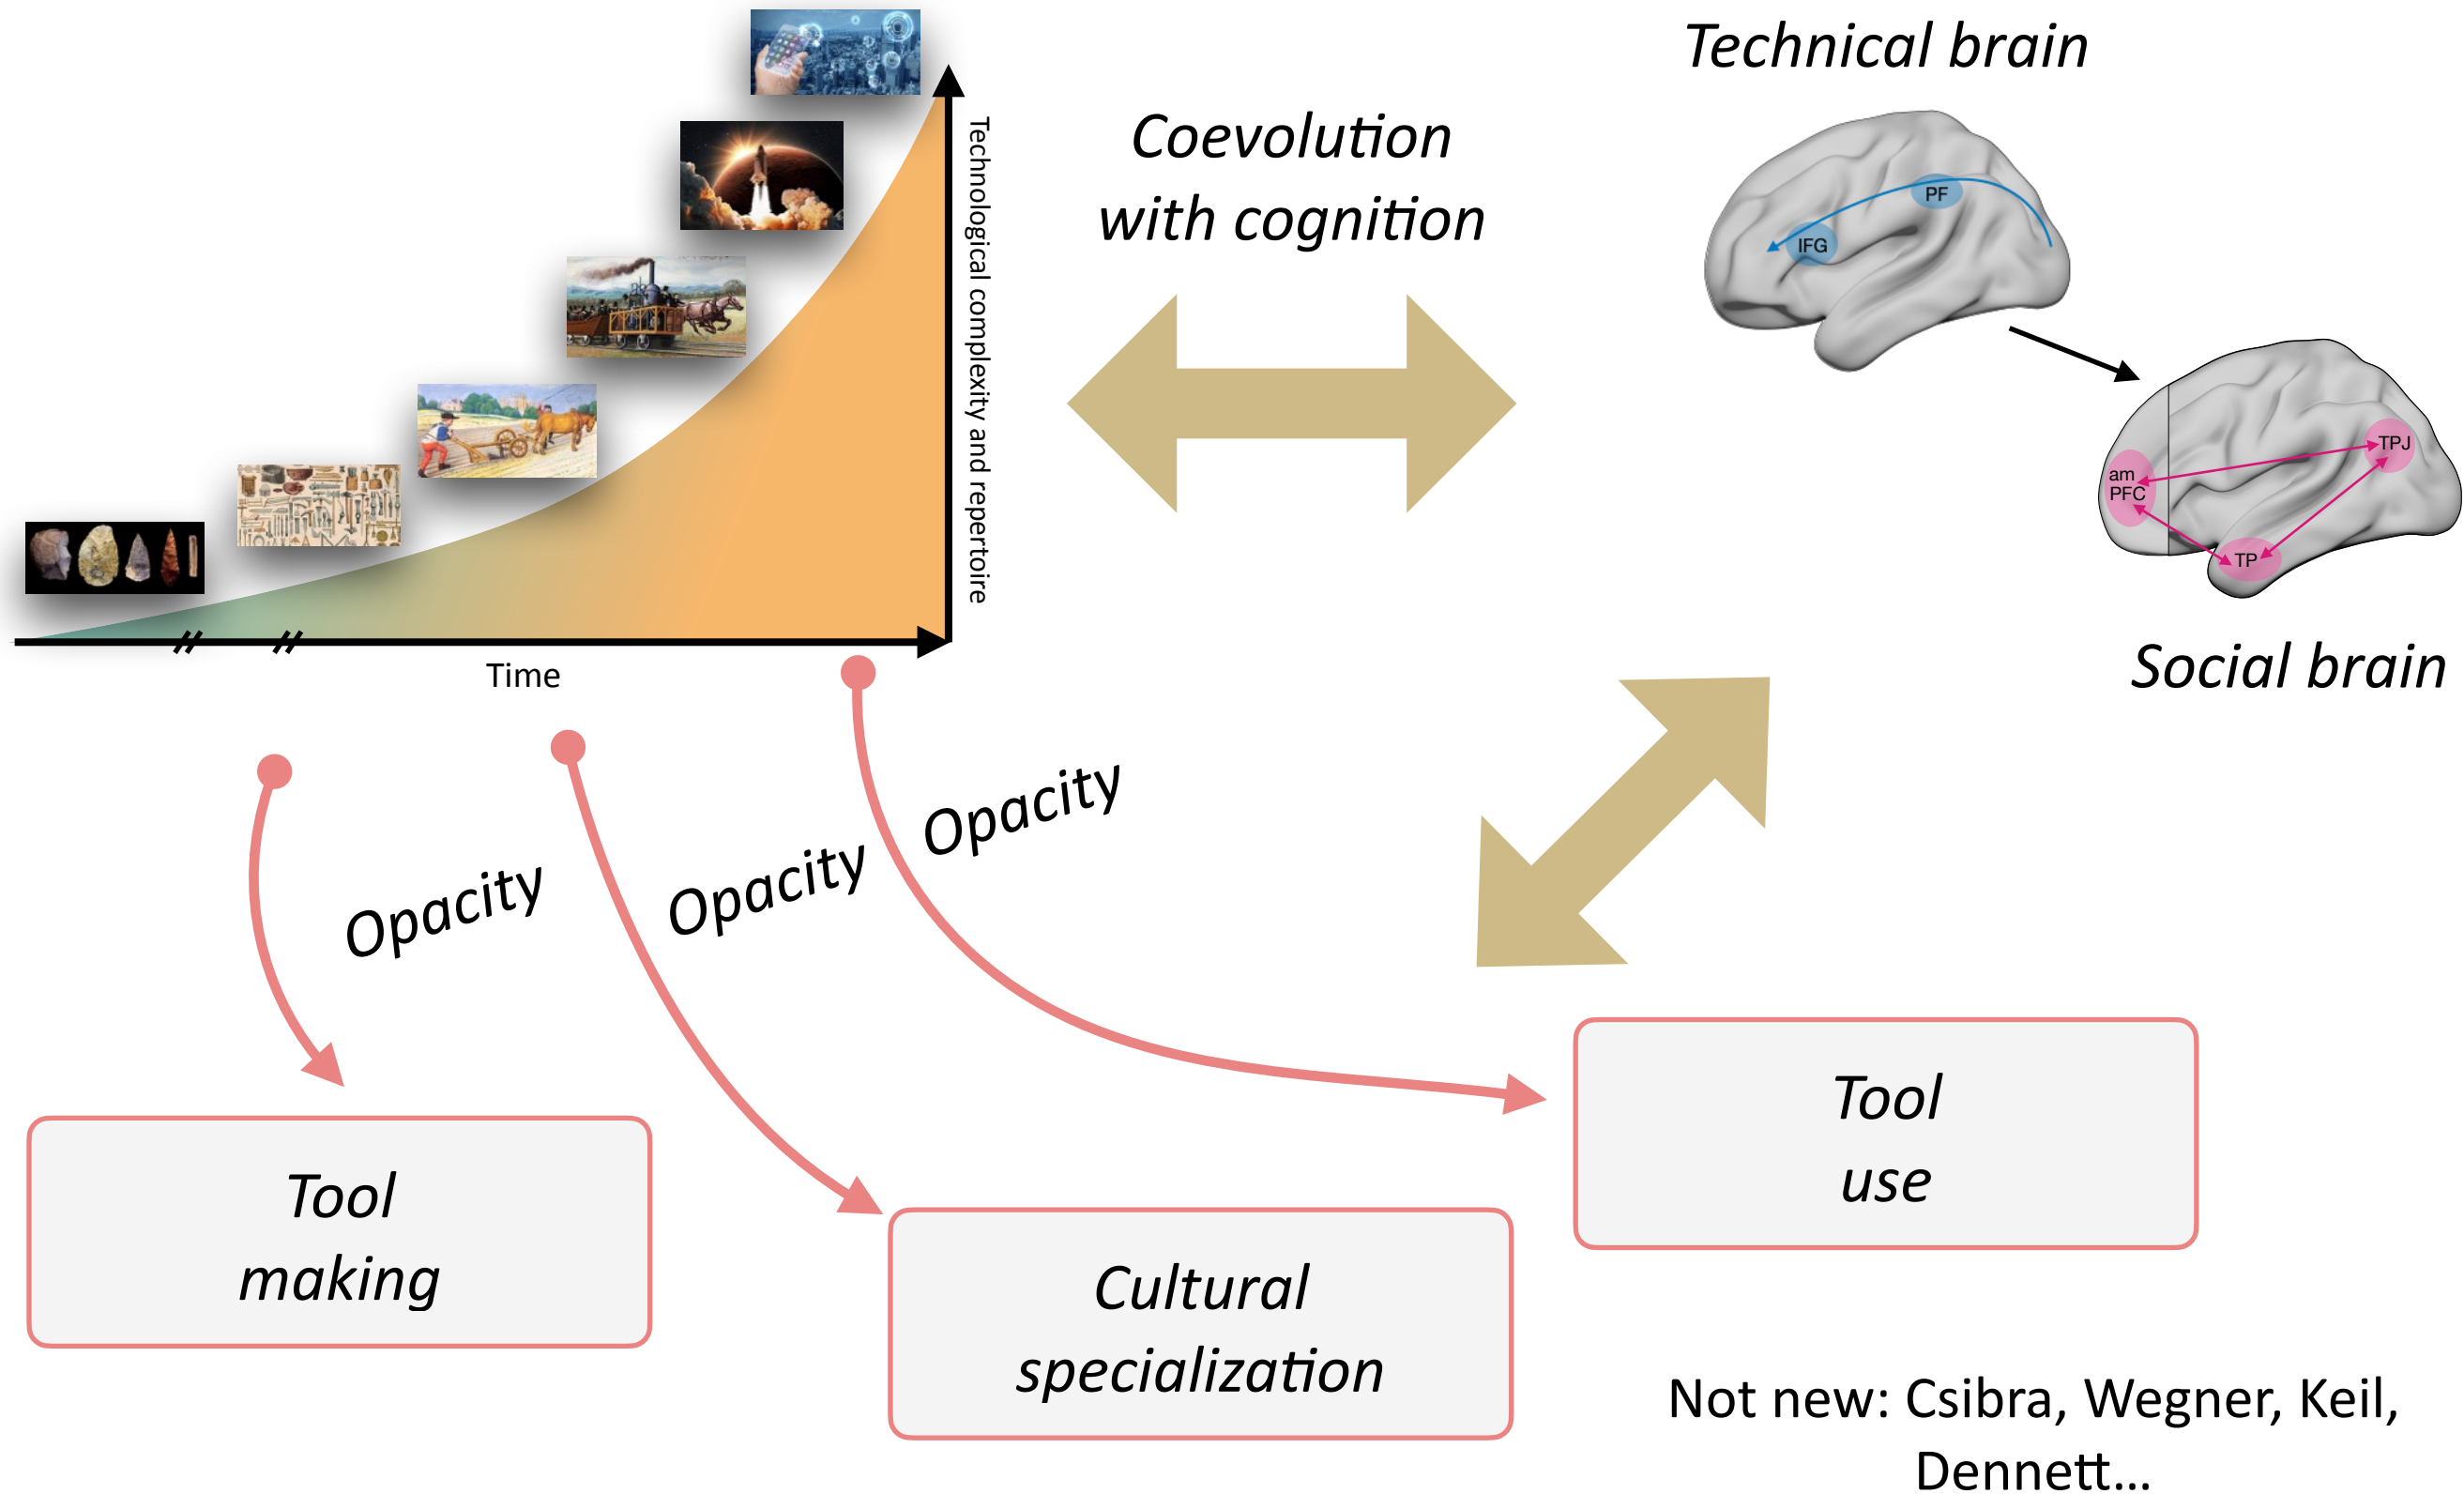

How does it work?

Making process

Transactive process

Using process

Overview

Technical versus social brain

Laws	Physical	Physical

Table 1. The computational goals and principles, representations, and cortical systems associated with naive physics and naive psychology. *Abbreviations:* TPJ (temporoparietal junction), SPL/IPL (superior and inferior parietal lobule), PMC (premotor cortex), PC (precuneus), MPFC (medial prefrontal cortex).

	Naive physics	Naive psychology
General computational goal	Explain, predict and intervene on...	
	... the physical states and motions of objects	...the mental states and behaviors of agents
Key representations	OBJECT: an inanimate permanent body that persists through space and time OBJECT PROPERTIES: position, shape, mass, material RELATIONAL PROPERTIES: express interactions between objects; contact, support, containment, adhesion KINEMATIC / DYNAMIC PROPERTIES: speed, velocity, force	AGENT: an animate entity that can change its own behaviors (i.e. act) at some cost, and has a perspective on (i.e. mental states about) the world MENTAL STATE: appraisal of a world state (e.g. cost, desire, emotion, knowledge, belief); in some cases a propositional attitude about that state (“she thinks the book is in the cabinet”) UTILITY: agents plan over this variable, composed of reward and cost
Causal law	Approximate Newtonian dynamics	Approximate rational planning
Judgments supported	Explanation: <i>Why?</i> ; Prediction: <i>What will happen next?</i> Counterfactuals: <i>What would have happened, if X were true?</i> Intervention: <i>What should I do, to make X happen?</i>	
	What is the mass, material, viscosity, and elasticity of this thing? Will it fall or stay stable? Why did it break, bounce, or flow the way it did?	What does she want, believe, or feel? What is she trying to do? Why did she do that?

Cortical systems	Network of regions spanning frontal and parietal cortices including premotor cortex, inferior and superior parietal lobule	Network of regions including the temporoparietal junction, superior temporal sulcus, precuneus, and medial prefrontal cortex
	<div>Regions associated with</div> <div><div>Physical Reasoning</div><div>Theory of Mind</div></div> <div><div><div>SPL</div><div>IPL</div><div>TPJ</div><div>PMC</div><div>STS</div></div><div><div>PC</div><div>MPFC</div></div></div>	

How physical information is used to make sense of the psychological world

Nature Reviews Psychology 5, 59–73 (2026) | [Cite this article](#)

A. Physical reasoning

Which way will it fall? More yellow or brown blocks?

N=32, $p < .001$ (FDR)

Schwettman et al. (2019)

B. Action Planning

Planning an action Looking at an object

N=19
0 20

Brandi et al. (2014)

C. Action Observation

Body movement Object movement

N=22
5 9

Ziccarelli et al. (2022)

These findings raise the possibility that the processes engaged by action observation, action planning and tool use, and physical reasoning may draw on a shared capacity: understanding how objects and agents (other people and ourselves) interact (see also ¹²⁰). These regions also exhibit strong intrinsic

fMRI reveals reciprocal inhibition between social and physical cognitive domains

Anthony I. Jack ^{a,*}, Abigail J. Dawson ^a, Katelyn L. Begany ^a, Regina L. Leckie ^a, Kevin P. Barry ^a, Angela H. Ciccio ^b, Abraham Z. Snyder ^c

A B S T R A C T

Two lines of evidence indicate that there exists a reciprocal inhibitory relationship between opposed brain networks. First, most attention-demanding cognitive tasks activate a stereotypical set of brain areas, known as the task-positive network and simultaneously deactivate a different set of brain regions, commonly referred to as the task negative or default mode network. Second, functional connectivity analyses show that these same opposed networks are anti-correlated in the resting state. We hypothesize that these reciprocally inhibitory effects reflect two incompatible cognitive modes, each of which may be directed towards understanding the external world. Thus, engaging one mode activates one set of regions and suppresses activity in the other. We test this hypothesis by identifying two types of problem-solving task which, on the basis of prior work, have been consistently associated with the task positive and task negative regions: tasks requiring social cognition, i.e., reasoning about the mental states of other persons, and tasks requiring physical cognition, i.e., reasoning about the causal/mechanical properties of inanimate objects. Social and mechanical reasoning tasks were presented to neurologically normal participants during fMRI. Each task type was presented using both text and video clips. Regardless of presentation modality, we observed clear evidence of reciprocal suppression: social tasks deactivated regions associated with mechanical reasoning and mechanical tasks deactivated regions associated with social reasoning. These findings are not explained by self-referential processes, task engagement, mental simulation, mental time travel or external vs. internal attention, all factors previously hypothesized to explain default mode network activity.
