Problem: generalization across studies

“You cannot play 20 questions with nature and win”

[Newell A. *Visual information processing*; 1973.]

- **Joint analysis**: Use large studies to inform small studies (“transfer learning”)
 - Principle: co-analyse studies, leverage joint representations
- **Mega-analysis**: find semantic commonalities across studies
 - Difficulty: what common vocabulary across studies?

**Large studies to inform analysis
of small studies:
*joint analysis***

Predictive modeling across datasets

Find good image annotations

Mining the neuroscientific literature

Need curated annotations

- Current ontology incomplete
 - Bigger limitation = lack of consistent vocabulary
- [Poldrack & Yarkoni, Annu Rev Psycho 2016]
- How to get those ?

Mining neuroimaging literature

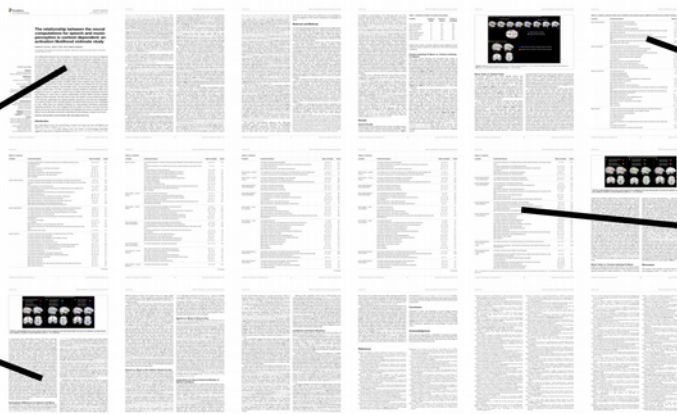

- Neuroimaging observations often stored in text.
- e.g “[...] in the anterolateral temporal cortex, especially the temporal pole and inferior and middle temporal gyri”
- Objectives:
 - transform neuroimaging publications into brain maps
 - meta-analysis of text-only corpora

“Text2brain”

Are visual texture-selective areas recruited during haptic texture discrimination?

Shape and texture provide cues to object identity, both when objects are explored using vision and via touch (haptics). Visual shape information is processed within the lateral occipital complex (LOC), while texture is processed in medial regions of the collateral sulcus (CoS). Evidence indicates that the LOC is recruited during both visual and haptic shape processing. Here we used functional magnetic resonance imaging (fMRI) to examine whether “visual” texture-selective areas are similarly recruited when observers discriminate texture via touch. We used a blocked design in which participants discriminated either the texture or shape of unfamiliar 3-dimensional (3D) objects, via vision or touch. We observed significant haptic texture-selective fMRI responses in medial occipitotemporal cortex within areas adjacent to, but not overlapping, those recruited during visual texture discrimination. Although areas of ventromedial temporal cortex are recruited during visual and haptic texture perception, these areas appear to be spatially distinct and modality-specific.

Importance of annotations

response execution, working memory, updating, body maintenance, visual body recognition,

response execution, right toe response execution,

visual arithmetic processing, sentence processing,

response selection, response execution, right finger response execution, visual tool recognition, grasping,

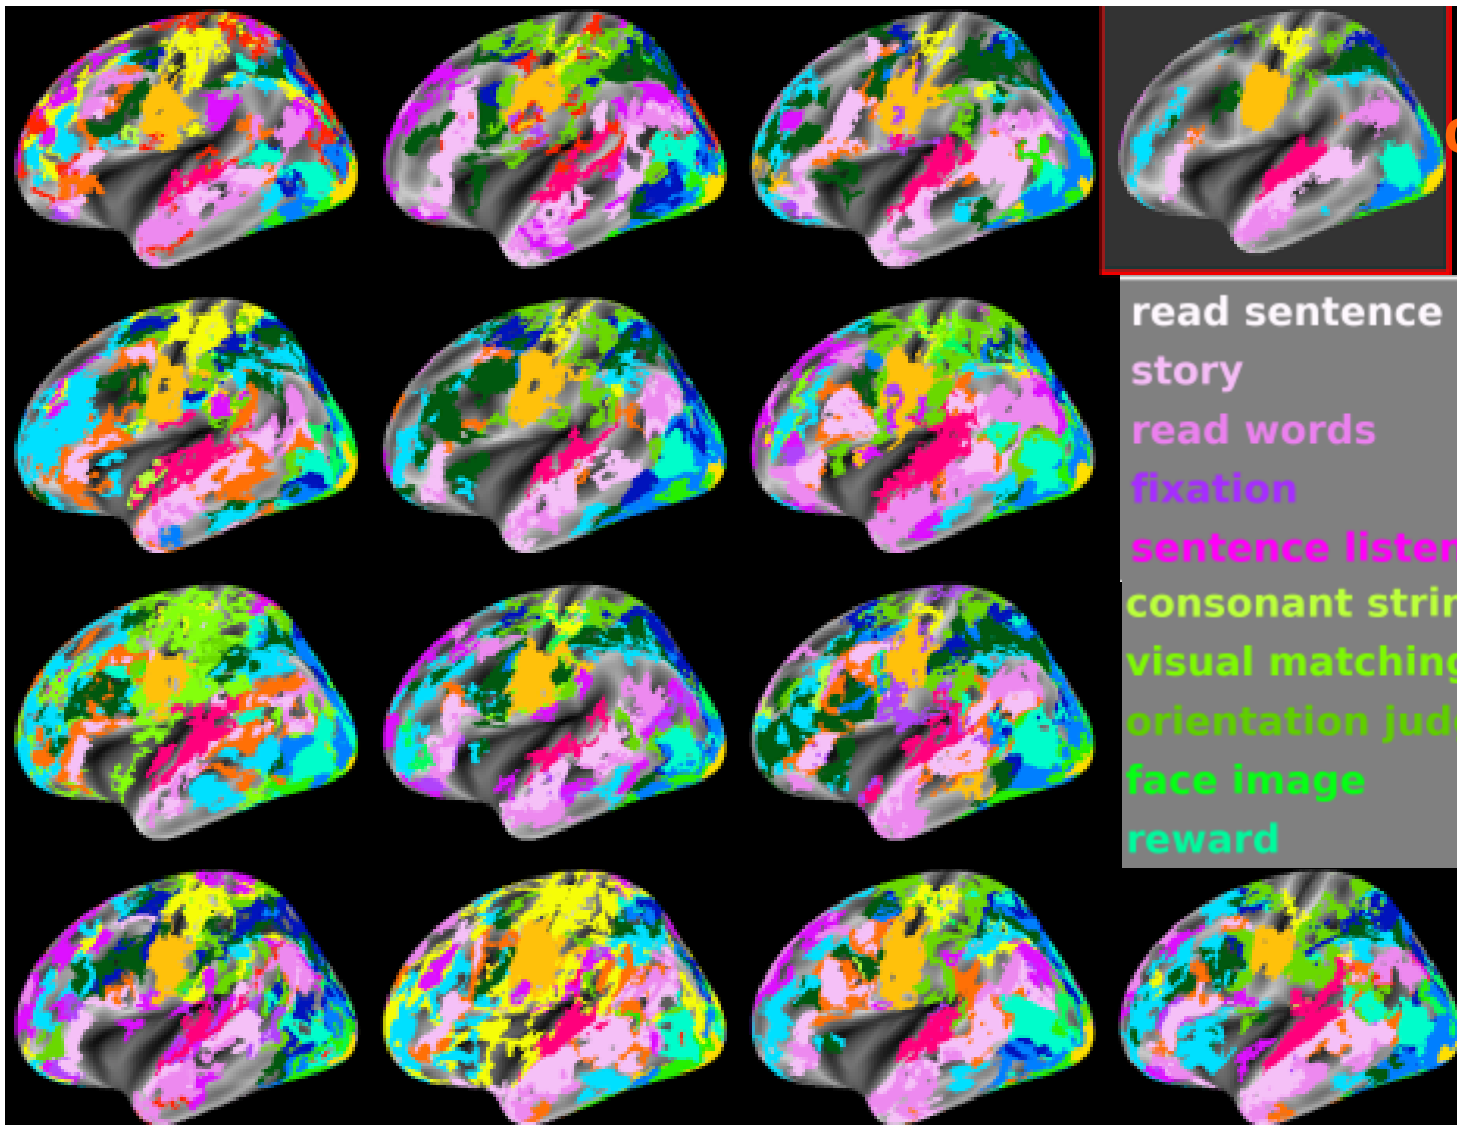

working memory, visual word recognition, word maintenance, sentence processing, syntactic parsing,

IBC in a nutshell

- 13 subjects
- About 30 acquisitions completed per subject
- Mostly fMRI, plus diffusion, relaxometry, high resolution anat
- 1.5mm isotropic resolution for fMRI
- Retinotopy, HCP/archi/Lyon/stanford batteries, free movie watching/story listening/language, social/pain/self localizer, valuation system, self, numerosity, mental time travel, tonotopy

Please share
your protocols !

IBC: deeper phenotyping

60 independent contrasts in 13 brains (200 more coming !)

Reproduce previous experiments

Structure underlying contrast maps

Prediction of the response for an unseen contrast, given other contrasts

Prediction per protocol and subject dependence

Highly subject-specific response and contrast between primary and associative areas

Conclusion

- Joint decoding/encoding for better **functional specificity**
- Finding **commonalities** across cognitive studies is hard
- Big data approach:
 - Extract **weak signals** from huge amounts of data
 - Common representation across datasets (*bottleneck*)

WIP

- **Structure underlying cognitive concepts**

From good ideas to good practices: software
